Author Note

This research was partially supported by the Work, Family and Health Network, which is funded by a cooperative agreement through the National Institutes of Health and the Centers for Disease Control and Prevention, National Institute of Child Health and Human Development (Grant # U01HD051217, U01HD051218, U01HD051256, U01HD051276), National Institute on Aging (Grant # U01AG027669), Office of Behavioral and Social Sciences Research, and National Institute for Occupational Safety and Health (Grant # U010H008788). The contents of this publication are solely the responsibility of the authors and do not necessarily represent the official views of these institutes and offices. Special acknowledgement goes to Extramural Staff Science Collaborator, Rosalind Berkowitz King, Ph.D. (NICHD) and Lynne Casper, Ph.D. (now of the University of Southern California) for design of the original Workplace, Family, Health and Well-Being Network Initiative. Persons interested in learning more about the Network should go to http://www.kpchr.org/workplacenetwork/. We thank Lillian Eby and several anonymous reviewers for helpful comments, Krista Brockwood for editorial assistance, and Michigan State University for additional research support of several graduate students who helped with coding.
Workplace Social Support and Work-Family Conflict: A Meta-Analysis Clarifying the Influence of General and Work-Family Specific Supervisor and Organizational Support

Abstract

This article uses meta-analysis to develop a model integrating research on relationships between employee perceptions of general and work-family specific supervisor and organizational support and work family conflict. Drawing on 115 samples from 85 studies comprising 72,507 employees, we compared the relative influence of four types of workplace social support to work-family conflict: perceived organizational support (POS); supervisor support; perceived organizational work-family support, also known as family-supportive organizational perceptions (FSOP); and supervisor work-family support. Results show work-family specific constructs of supervisor support and organization support are more strongly related to work-family conflict than general supervisor support and organization support, respectively. We then test a mediation model assessing the effects of all measures at once and show positive perceptions of general and work-family specific supervisor support indirectly relate to work-family conflict via organizational work-family support. These results demonstrate that work-family specific support plays a central role in individuals’ work-family conflict experiences.

Workplace Social Support and Work-Family Conflict: A Meta-Analysis Clarifying the Influence of General and Work-Family Specific Supervisor and Organizational Support

An increasingly important area of human resource management (HRM) research involves not only examining formal HR policies, but informal employee perceptions of support at work. For example, although early work-family (W-F) research emphasized how employees’ access and use of formal workplace supports (i.e., work-family policies, such as on-site child care) can reduce work-family conflict (e.g., Goff, Mount & Jamison, 1990; Kossek & Nichol, 1992), in recent years, the field has shifted to emphasize informal workplace support, such as a supervisor sympathetic to work-family issues (Hammer, Kossek, Yragui, Bodner & Hanson, 1999; Thomas & Ganster, 1995) or a positive work-family organizational climate (Allen, 2001).

Many new human resource management trends heightening workplace stress have made it critical for personnel psychologists and managers to better understand informal workplace social support linkages to work-family conflict. These include: shifting labor market demographics to include more workers that value work-life flexibility such as, parents, millenials, older workers; rising work hours and workloads distributed on 24-7 operating systems, sharpening the pace and intensity of work; and escalating financial, market and job insecurity from the global economy (Kossek & Distelberg, 2009). Despite the growing importance of understanding workplace social support linkages to work-family conflict due to these rising pressures, research has yet to fully clarify: 1) what type of social support (general or work-family specific), either from supervisory or organizational sources, is most strongly related to work-family conflict; and 2) the processes by which these types of support relate to work-family conflict.
In this meta-analysis, we integrate theory from the broader social support (Caplan, Cobb, French, Harrison, & Pinneau, 1975), perceived organizational support (Eisenberger, Huntington, Hutchison, & Sowa, 1986), and work-family stress literatures (Bakker & Demeroutti, 2007; Hofboll, 1989) to address these gaps. We develop and test a model of the mediating effects of perceived organizational support (general and work-family specific) on the relationship between supervisor support (general and work-family specific) and work-to-family conflict. Our study advances findings from previous meta-analyses which found that relationships between general work support and family and job satisfaction are partially mediated by work-family conflict (Ford, Heinen, & Langkamer, 2007) and that social support is an antecedent of role stressors and ultimately work-family conflict (Michel, Michelson, Pichler, Cullen, in press). While these meta-analyses are valuable additions, none examined relationships between all four of the most widely assessed types of workplace social supports and work-family conflict separately or in an integrated path analytic model. By addressing these issues, our research has key implications for the work-family field theoretically (increasing understanding of the nomological net of social support and work-family conflict) and practically (identifying the types of support employers and managers should develop and reinforce).

Workplace Social Support and Work-Family Conflict

Construct Definitions and Linkages

Work-family conflict. Work-family conflict is a form of inter-role conflict that occurs when engaging in one role makes it more difficult to engage in another role (Kahn, Wolfe, Quinn, Snoek, & Rosenthal, 1964). It is a growing type of stress for most employees in the U.S. (Aumann & Galinsky, 2009) and internationally (Poelmans, 2005).
Work-family conflict is an important antecedent of job and life effectiveness, as many reviews show it is associated with a wide range of positive and negative work, family, and stress-related outcomes (Allen, Herst, Bruck, & Sutton, 2000; Eby, Casper, Lockwood, Bordeaux, & Brinley, 2005; Kossek & Ozeki, 1998). Based on theoretical grounding showing that a lack of workplace social support is most likely to impact work-to-family conflict in the direction of the work role interfering with the family role (cf. Frone, Russell & Cooper, 1992), we focused this meta-analysis on studies measuring relationships between workplace social support and work-to-family conflict.

*Workplace social support.* The concept of workplace social support is derived from the broader social support literature. It is typically viewed as a global construct (House, 1981) with a range of definitional dimensions that fluctuate in meaning. One of the most widely used and earliest definitions comes from Cobb (1976) who defined social support as an individuals’ belief that she is loved, valued and her well-being is cared about as part of a social network of mutual obligation. Others have viewed social support as involving perceptions that one has access to helping relationships of varying quality or strength, that provide resources such as communication of information, emotional empathy, or tangible assistance (Viswesvaran, Sanchez, & Fisher, 1999). Our review suggested that both of these core ideas of 1) feeling cared for and appreciated; and 2) having access to direct or indirect help have been used in the social support literature, often combined in global measures. Regardless of the items used, we assume that social support is a critical job resource that makes the role demands for which support is given such as the integration of the work-family interface experienced more positively.
Workplace social support is defined as the degree to which individuals perceive that their well-being is valued by workplace sources, such as supervisors and the broader organization in which they are embedded (Eisenberger, Singlhamber, Vandenberghe, Sucharski, & Rhoades, 2002; Ford, et al, 2007), and the perception that these sources provide help to support this well-being. We conceptualize workplace social support as 1) emanating from multiple sources, such as supervisors, coworkers, and employing organizations; and 2) distinguished by different types or foci of support that are either “content-general” or ”content specific”. General work support is the degree to which employees perceive that supervisors or employers care about their global well-being on the job through providing positive social interaction or resources. Content-specific support relates involves perceptions of care and the provision of resources to reinforce a particular type of role demand. We examine work-family specific support, the degree to which employees perceive supervisors or employers care about their ability to experience positive work-family relationships and demonstrate this care by providing helpful social interaction and resources. Examples of general and content specific support are below.

**General supervisor support and supervisor work-family support.** General supervisor support involves general expressions of concern by the supervisor (i.e., emotional support) or tangible assistance (i.e., instrumental support) that is intended to enhance the well-being of the subordinate (c.f., House, 1981). While general supervisor support focuses on support for personal effectiveness at work, supervisor work-family support facilitates the employee’s ability to jointly manage work and family relationships.

---

1 This study did not include measures of coworker support, work-family policies, family-to-work conflict or work-family enrichment due to too few samples in the literature.
Supervisor work-family support is defined as perceptions that one’s supervisor cares about an individual’s work-family well being, demonstrated by supervisory helping behaviors to resolve work-family conflicts (Hammer et al, 2009) or attitudes such as empathy with one’s desire for work-family balance (Thomas & Ganster, 1995).

*Perceived organizational support and organizational work-family support.*

Organizational support theory holds that individuals personify organizations by attributing human-like characteristics to them, and that they develop positive social exchanges with organizations that are supportive (Eisenberger, Armeli, Rexwinkel, Lynch & Rhoades, 2001). Perceived organizational support (POS) (Eisenberger et al., 1986) refers to employees’ overall beliefs regarding the degree to which an employer values employees, cares about their well-being, and supports their socio-emotional needs by providing resources to assist with managing a demand or role. Perceived organizational support can also be content specific to a domain such as employees’ family-supportive organizational perceptions (FSOP), the degree to which an organization is seen as family-supportive (Allen, 2001). We build on this work and define organizational work-family support as perceptions that one’s employer 1) cares about an employee’s ability to jointly effectively perform work and family roles and 2) facilitates a helpful social environment by providing direct and indirect work-family resources. Examples are a work-family climate (indirect support) where workers feel they do not have to sacrifice effectiveness in the family role to perform their jobs and can share work-family concerns (cf., Kossek, Colquitt & Noe, 2001), and perceived access to useful work-family policies (direct support). Three hypotheses guide this meta-analysis, which are explained with rationale below.
Hypotheses

Supervisor and organizational support linkages to work-family conflict. When examined separately, we expect that both general and work-family specific workplace support will have a direct and negative relationship with work-to-family conflict. The rationale for this hypothesis draws on and integrates assumptions from social support (Caplan et al., 1975; House, 1981), and conservation of resources (COR) (Hobfoll, 1989) and job-demands-resources (JD-R) theories (Karasek, 1979). The primary tenets of COR theory are that individuals strive to gain and maintain resources that are valuable to them and that resource loss has a greater psychological impact than does resource gain as related to stress. A key proposition of the JD-R model is that interactions between job demands and resources are important, such that certain resources (e.g., social support) can mitigate the negative psychological effects (e.g., burnout) of stress.

Since work-to-family conflict is a situation where the demands of the work role deplete resources (e.g., time, energy, emotions) required to participate in the family role (Lappiere & Allen, 2006), individuals with greater access to workplace social support garner additional job psychological resources (cf., Bakker & Demorouti, 2007) that providing a stress buffer to manage strain. When individuals feel socially supported at work, they feel cared for by social others and feel that they have access to help (Cohen & Wills, 1985; Hobfoll, 1989). As individuals perceive more social support, their emotional and psychological supplies for coping with daily stressors increase, and perceptual appraisals of stressors decrease (Jex, 1998). When individuals have more social support in general and content specifically for managing work-family issues, these
positive dynamics may spillover into the family role thereby reducing work to family conflict (e.g., Frone et al., 1992).

Hypothesis 1: Perceptions of workplace social support both general (perceived organizational support, supervisor support) and work-family specific (organizational work-family support, supervisor work-family support) will be negatively related to work-to-family conflict.

General vs. work-family specific support linkages to work-family conflict. We expect that work-family specific support will have a stronger relationship with work-to-family conflict than will general workplace support. The rationale for this proposition is based on the assumption that work-family specific support is likely to be a more psychologically and functionally useful resource to manage work-family stressors, such as time, strain or behavior-based conflicts, the main theoretical components of work-family conflict (Greenhaus & Beutell, 1985) than general workplace social support.

Work-family research has shown that trying to manage demands from multiple roles (i.e., work and family) leads to reduced resources and, increased strain in the form of work-to-family conflict (Grandey & Cropanzano, 1996). Work-family specific social support goes a step further than general support, in that it not only buffers stress from job demands, but helps to conserve resources in both the work and family domains (Allen, 2001) by providing support specifically directed at balancing demands from both spheres (Hammer et al., 2009; Thomas & Ganster, 1995). For example, supervisors providing work-family specific support will be viewed as caring more about work-family well-being and providing more help to ensure work-family effectiveness than supervisors who are only generally supportive for the work role. As a result, employees with greater access to work-family specific support will feel they have more work-family specific psychological resources than those with general support. Employees will be more likely
to feel comfortable discussing work-family problems with supervisors perceived as providing a lot of work-family specific support or asking for greater flexibility or autonomy to better manage the work-family interface. This will enable employees who perceive they have high work-family specific support, to feel in greater control of work-family demands, and perceive they have more content relevant resources to manage work-family conflicts than those who only perceive they have general supervisor support.

Granted, certainly perceiving one has a generally supportive supervisor who cares about one’s overall well-being is a resource. However, theory suggests general support will be less strongly related to work-family conflicts. For example, general support may not necessarily give workers more autonomy over where and when the work role is done to handle work-family demands; increase employee access to or communication of information on work-family policies; or provide a sounding board for openly discussing work-family conflicts (Thomas & Ganster, 1995). Similarly, organizations perceived as providing greater work-family specific support will be more likely to be perceived as valuing employee well-being not only at work, but also at home, and as providing more helpful work-family specific resources such as work-family policies that can be used without backlash than those providing just general organizational support.

Besides theoretical reasons, construct measurement rationale also supports stronger relationships between work-family conflict and work-family specific support compared to general workplace support. We draw on a bandwidth fidelity argument from measurement experts arguing that the breadth, of the predictor and criterion should be congruent in order to have a stronger correlation or association with each other (Hogan &
Holland, 2003). Indeed, a recent validation study found work-family specific support to be significantly related to lower work-family conflict over and above a general measure of supervisor support (Hammer et al, 2009).

Hypothesis 2: Perceptions of work-family specific support will be more strongly related to work-to-family conflict than general perceptions of workplace social support. Work-family specific supervisor support will be more strongly related to work-to-family conflict than will general supervisor support, and family-supportive organizational perceptions will be more strongly related to work-to-family conflict than will perceived organizational support.

Model of relationships between different support types and sources and work-to-family conflict. No existing research has integrated an examination of the relationships between different types of social support across supervisor and organizational sources as related to work-to-family conflict in a single model. This is a significant omission because, in a simultaneous model, one type (general or work-family specific) or source (organizational or supervisor) of support may become a more or less important predictor of work-family conflict when controlling for other types and sources of support. While direct relationships in relation to WFC are posited when different types and sources of support are examined separately, when all forms of support are examined simultaneously, we expect that perceived organizational support (general and wf-specific) will mediate relationships between general and wf-specific supervisor support and work-to-family conflict.

Toward this end, we develop a mediation model to examine interrelationships between work-to-family conflict and different types of workplace social support (general, and work-family specific) simultaneously. We argue that workplace social support and work-family conflict constructs comprise an important inner-related employee-employer
social system. Organizational support theory contends that employee perceptions of supervisor support contribute to perceptions of organizational support (Eisenberger et al., 1986; 2002). Because a supervisor acts as a representative of the organization, assuming a supervisor has respect, (Eisenberger et al., 2002), his/her supportiveness will lead an employee to be more likely to perceive the organization as supportive. Rhoades and Eisenberger (2002) documented that perceptions of organizational support mediate relationships between supervisor support and outcomes relevant to this study such as strain. Further work by Eisenberger and colleagues (2002) found that supervisor support contributed to temporal change in organizational support (but not vice versa); and POS fully mediated the relationship between supervisor support and turnover. These results suggest that supervisor support is related to POS, and that the latter is often a mediator for supervisor support and employee work-family related outcomes (strain).

Extending this view, Allen (2001) proposed that perceptions of organizational work-family support will mediate relationships between supervisor work-family support and similar work-related outcomes. Indeed, Allen (2001) found that organization work-family support completely mediated the relationship between supervisor support and work-family conflict. Overall, existing theory and research (e.g., Behson, 2002) would suggest that both types of organizational support will mediate the relationships between both types of supervisor support and work-family conflict.

Hypothesis 3: Perceptions of organizational support (general and work-family specific) will mediate the relationships between supervisor support (general and work-family specific) and work-to family conflict.

Method

Inclusion Criteria and Literature Search
We included studies that i) measured workplace social support, ii) measured work-to-family conflict and iii) reported sufficient information to compute an effect size. We obtained both published and unpublished studies through four methods. First, we conducted an extensive computerized search of the PsycINFO Business Source Elite, Academic Search Elite, Sociological Abstracts, and the Academy of Management archive databases from their inception, which is as early as 1905 for PsycINFO, through April 2010. We used using the following keywords: “supervisor support,” “organizational support,” “social support,” “work and life,” work-home, work-family interference, and “work-family conflict.” Second, we conducted a computerized search of the Society for Industrial-Organizational Psychology’s and the Academy of Management meetings online databases, and the Dissertation Abstracts International database for unpublished studies through April 2010 using the same key words. We also did manual searches of journals, such as Personnel Psychology, Journal of Applied Psychology, Academy of Management Journal, Organizational Behavior, and Human Decision Processes, as a check on our computerized search. Finally, we sent out emails on list serves inviting unpublished work. We also invited authors to send us unpublished studies at the end of a presentation of an earlier version of the paper at a national conference (SIOP), in order to increase sample size during writing revisions. This process yielded 115 samples from 85 studies comprising 72,507 employees for inclusion, which are noted in the Appendix.

**Study Coding**

To establish reliability of coding, two graduate students independently coded the studies. Given our interest in how general and work-family specific workplace social supports are related to work-family conflict, these individuals independently coded
whether measures reflected supervisor or organizational support, and whether they were
general or specific to the work-family context. Coding was based on scale descriptions
and/or sample items provided either in the included studies or in separate published
validation studies. Agreement was 100% for the source (supervisor vs. organization), and
95% for the type (general vs. work-family specific) of support. Disagreements were
resolved after discussion.

Meta-Analytic Procedures

Effect size metric and modeling procedures. The effect size metric chosen was
the correlation coefficient. Our meta-analytic procedures followed conventional model
meta-analytic techniques for tests of effect size centrality and homogeneity (Hedges &
Olkin, 1985; Hedges & Vevea, 1998); use random-effects models throughout; and Z-tests
for tests of effect size centrality (cf. Lipsey & Wilson, 2001).

Correlations were transformed into the Fisher correlation metric for analysis.
These were then back-transformed into the correlation metric. For estimation and testing,
we weighted each effect size by the inverse of its sampling variance giving greater weight
to studies with greater estimation precision. We did not apply any other effect size
corrections because this approach can lead to inaccurate conclusions about the effect size
population mean and variability (DeShon, 2002). As shown in Figure 1 below, we tested
two meta-analytic path models (Viswesvaran & Ones, 1995) to determine if perceived
organizational support and organizational work-family support mediated the relationships
between supervisor support and supervisor support for family, and work-family conflict.
Consistent with existing research (Carr, Schmidt, Ford, & DeShon, 2003), we used mean
meta-analytic correlations as input along with smallest sample size on which these mean
Workplace Social Support and Work-Family Conflict

correlations were based. Using AMOS 5.0, we evaluated model fit using a variety of fit statistics including chi-square, CFI and RMSEA. CFI values greater than .97 and RMSEA values less than .05 were used to indicate good fit (Kline, 2005).

*Nonindependent effect sizes.* Since some work-to-family and social support measures can have multiple dimensions, several studies contributed multiple relevant, but non-independent effect sizes. For instance, work-to-family conflict is often measured as time-, strain- and behavior-based (Greenhaus & Beutell, 1985), and social support can be measured as emotional, informational and instrumental (House, 1981). Similar to previous studies of support in the workplace (e.g., Rhoades & Eisenberger, 2002), whenever a study provided multiple effect sizes due to measuring work-to-family conflict or support at work using multiple uni-dimensional subscales, these effect sizes were transformed into a correlation of composite variables (see Hunter & Schmidt, 1990) and were treated as a single effect size (Lipsey & Wilson, 2001; Rosenthal and Rubin, 1986).

**Results**

Table 1 presents the bivariate meta-analytic results. Consistent with Hypothesis 1, work-to-family conflict was negatively and significantly correlated with organizational support (typically measured by POS) ($M_r = -.22, Z = 4.83, p < .001$), organizational work-family support (typically measured by FSOP) ($M_r = -.36, Z = 13.80, p < .001$), supervisor support ($M_r = -.15, Z = 6.39, p < .001$), and supervisor work-family support ($M_r = -.25, Z = 19.16, p < .001$). The magnitude of the mean correlations ranged from *small* to *medium* in size (Cohen, 1987). Thus, Hypothesis 1 was supported.

Consistent with Hypothesis 2, the mean correlation between work-to-family conflict and supervisor work-family support ($M_r = -.25$) was significantly stronger than
the mean correlation between work-to-family conflict and general supervisor support ($M_r = -.15$), $\chi^2(1) = 10.07, p = .002$. In addition, the mean correlation between work-to-family conflict and organizational support work-family support ($M_r = -.36$) was significantly stronger than the mean correlation between work-to-family conflict and general organizational support ($M_r = -.22$), $\chi^2(1) = 6.13, p = .01$.

An alternative approach to test Hypotheses 2 is to explore the unique effect of each support type on work-family conflict by including both general and family-specific forms in a multiple regression model predicting work-family conflict using as input the meta-analytic correlations presented in Table 1. The primary questions for these models were 1) to explore whether the observed, significant relationships between each support type and work-family conflict remained when controlling for the other type of support and 2) to test whether a model that constrained these unique relationships to equality fit the data well. Controlling for perceived organizational support, organizational work-family support remained significantly and negatively related to work-family conflict ($b = -.32, Z = -11.22, p < .001$). Controlling for organizational work-family support, perceived organizational support remained significantly and negatively related to work-family conflict ($b = -.11, Z = -3.72, p < .001$). To test whether these partial relationships differed significantly, we compared the fit of a model that constrained these partial relationships to equality to the model where both relationships were freely estimated. The constrained model fit significantly worse than the unconstrained model, $\Delta \chi^2 (1, N = 1,188) = 20.62, p < .001$. Therefore, the partial relationship between perceived organizational work-family support and work-family conflict is greater in magnitude than the partial relationship between general organizational support and work-family conflict.
Controlling for general supervisor support, supervisor work-family support remained significantly and negatively related to work-family conflict \((b = -0.24, Z = -5.44, p < .001)\). However, controlling for supervisor work-family support, general supervisor support was no longer significantly related to work-family conflict \((b = -0.02, Z = -0.33, p = .74)\). To test whether these partial relationships differed significantly, we compared the fit of a model that constrained these partial relationships to equality to the model where both relationships were freely estimated. The constrained model fit significantly worse than the unconstrained model, \(\Delta \chi^2 (1, N = 691) = 8.32, p = .004\). Therefore, the partial relationship between work-family supervisor support and work-family conflict is greater in magnitude than the partial relationship between general supervisor support and work-family conflict. Taken together, these results support Hypothesis 2.

Path model testing the mediating role of perceptions of organizational support and organizational work-family support. Hypothesis 3 predicted that organizational support and organizational work-family support would mediate the relationships between both supervisor support and supervisor work-family support and work-to-family conflict. Given that these predictors of work-to-family conflict are all positively correlated, we deemed it prudent to test these hypotheses in the context of a unified meta-analytic path model (Viswesvaran & Ones, 1995).

Before testing the model of interest, we estimated a just-identified model with paths from each type of supervisor support to each type of organization support, as well as to work-to-family conflict, and with paths from each type of organization support to work-to-family conflict. Figure 1 presents the parameters of this model where significant paths are marked with an asterisk. Whereas the nonsignificant path between supervisor
Workplace Social Support and Work-Family Conflict

support and work-to-family conflict was consistent with our mediation hypotheses \((b = .09, Z = 1.76, p = .08)\), the significance of two parameters in this model were not expected. First, supervisor work-family support had a significant direct effect on work-to-family conflict \((b = -.17, Z = 3.50, p < .001)\); second, organizational support had a nonsignificant direct effect on work-to-family conflict \((b = -.08, Z = 1.67, p = .10)\).

Using this information and for parsimony, we pruned the model to omit the nonsignificant paths. Figure 2 presents the parameters of this pruned model where significant paths are marked with an asterisk. This model fit the data well, \(\chi^2(2, N = 609) = 5.50, p = .06, GFI = .99, CFI = .99, RMSEA = .05\), and did not differ significantly from the just-identified model, \(\Delta\chi^2(2, N = 609) = 5.50, p = .06\). Note that in this model, there is no path between organizational support and work-to-family conflict when controlling for the other predictors in the model. Thus, organizational support cannot mediate the impact of supervisor support on work-to-family conflict. Furthermore, supervisor work-family support has a significant, negative direct relationship to work-to-family conflict when controlling for the other predictors \((b = -.15, Z = -3.81, p < .001)\). These results contradict Hypothesis 3. However, two results suggest partial support for facets of Hypothesis 3. First, this model implies that supervisor support did not have a significant direct effect on work-to-family conflict when controlling for the other predictors. Second, using the Sobel test, we found a negative, significant indirect relationship of supervisor work-family support to work-to-family conflict through organizational work-family support \((Z = -5.50, p < .001)\). Interestingly, using the Sobel test, we found a significant, negative indirect relationship of supervisor support to work-to-family conflict through organizational work-family support \((Z = -6.79, p < .001)\). Overall, our findings
suggest that organizational work-family support plays a critical mediating role in the relationships between supervisor support and work-to-family conflict and supervisor support for family and work-to-family conflict. Additionally, work-family specific support at both the supervisor and organizational level are strongly related to work-to-family conflict, when controlling for general social support from these sources.

Discussion

The purpose of this article was to i) test whether or not work-family specific workplace social support is more strongly related to work-family conflict than general support, ii) develop and test a path model of the interrelationships between different types and sources of workplace social support as related to work-family conflict in a single, simultaneous model. In testing our path model where we theorized that the relationship between supervisor support (both general and work-family specific) and work-to-family conflict was mediated by organizational support (both general and specific), we found that the meditational effects only held up for work-family specific organizational support (Figure 2). In other words, both general and work-family supervisor support were related to work-to-family conflict via work-family organizational support. Further, supervisor work-family support had a direct relationship with work-to-family conflict, when controlling for work-family organizational support. These results suggest that both work-family organizational support and work-family supervisor support (both directly and via work-family organizational support for the latter) are related to work-to-family conflict.

The partial mediation findings indicate that work-family specific organizational support is not the only mechanism though which work-family specific supervisor support relates to work-family conflict. These results do not challenge the fact that positive
perceptions of work-family specific organizational support are strongly related to work-family conflict reduction. Rather there are other unmeasured mediating variables than direct supervisor support effects that may be useful in alleviating work-to-family conflict. These may include decreasing job demands, workloads, and tight deadlines; and increasing employee perceptions of control over the timing and location of work through structural job design (Karasek, 1979). These are all potential factors that organizations and supervisors can influence.

_Workplace Social Support and Work-family Literature Implications_

Overall, our results provide a clear pattern: that the form or _type_ of workplace social support (whether it is general or content, i.e., work-family specific) that an employee receives from the workplace matters for work-family conflict, as does the _source_ of support (i.e., supervisor or organization). Work-family specific support seems to operate differently in terms of its relationship with work-to-family conflict than general support, according to whether the source is the organization or supervisor. As a result, this study shows how important it is in future research for scholars to take care in construct definition and measurement related to workplace social support and work-family conflict linkages. Currently, work-family studies sometimes are unclear in or confound the referent used (e.g., organization or supervisor; general or content-specific support) in the same construct, which should be avoided (c.f., Thompson et al., 1999).

A key implication of the path analytic findings is that when it comes to linkages between perceptions of general social support and work-family conflict, it is important for employees to feel that their organization cares about reducing work-family conflicts and that they are provided adequate resources to both do their job and manage their
Workplace Social Support and Work-Family Conflict

nonwork demands (Eisenberger et al., 1986). However, when it comes to perceptions of support for work and family and the relation to work-family conflict, it is potentially more important for supervisors to enact specific behaviors that are supportive of employees’ ability to balance work and family (Hammer et al., 2009; Thomas & Ganster, 1995) than it is for them to enact more general socially supportive behaviors (Caplan et al., 1975). The rationale for the recommendation is that this study clearly demonstrates that supervisors are the mechanism for shaping views of general and work-family specific support and its association with work-family conflict.

Future research should focus on the supervisor’s role in the enactment of HR practices to manage newer and evolving workforce issues such as work and family relationships. It is only relatively recently work-family issues have entered the workplace as a mainstreamed supervisor leadership role (Kossek, Lewis & Hammer, 2010). Many supervisors and firms are still in transition in shifting behaviors and cultures to be more explicitly supportive of work and family. New studies are needed to explicitly capture these managerial and organizational learning processes.

None of the studies in our database considered how perceptions of workplace support cascade across levels of analysis from supervisors to organizations to employee work-family conflict experiences. Longitudinal multi-level studies should increasingly include measures of both general and work-family specific supervisor and POS. With few exceptions (i.e., Thompson et al., 2004), work-family research neglects important cross-level or support relationships. Given the need for more multi-level work-family research, future studies should be conducted with further construct clarity in distinguishing between the measurement of supervisor and co-worker support at the work
Workplace Social Support and Work-Family Conflict

group level, and organizational support at the cultural and policy levels. All of the studies we examined measured support at the individual perceptual level. Different types of support from different sources may have specific impacts on differential types of conflict and different mediators or moderators. For example, supervisor or co-worker support may have a stronger relationship to work-family conflict in a high performance teamwork environment where the tasks are highly interdependent and employees learn to rely on one another, or cross-train to back each other up, than organizational support. Future research on workplace social support theory should also be further developed to theorize the conditions under which content specific compared to content general workplace support matters more for positive employee outcomes. Theories need to be enhanced to understand processes making the source of the support relevant or not and why, such as whether coworker or team support can substitute for supervisor support, and in what contexts. For example, cultural contexts may vary and future studies should also include analysis of cross-cultural contextual differences, as nationalities may vary in what types and sources of support are likely to be most strongly related to work-family conflict.

*Omitted Variables*

This study did not include measures of coworker support, work-family policies, family-to-work conflict or work-family enrichment due to too few samples in the literature. Future studies clearly need to focus on these measures as a larger body of work accumulates. As employers move toward more virtual teams, and continue to flatten, it is critical to include measures of coworker support (general and work-family specific). Work-family enrichment (the degree to which w-f roles are positively experienced as complimentary) should also be included so research can assess not only how jobs relate
to negative personal outcomes at home, but how work and work-family interactions can also be beneficial in personal lives. We also need studies to include more unmeasured variables that might mediate the relationship between supervisor support and work-family conflict (job demands, job control, workloads, and backlash for using flexibility).

**Implications for Practice**

Our critical assessment of the existing research has practical value as it helps organizations understand what types of workplace social support (i.e., work-family specific) leaders and employers should invest in to reduce work-family conflict and which sources (i.e., supervisors) are likely to be most effective (Hammer et al., 2009). Longitudinal research suggests (Hammer et al., in press) there are many strategies that an organization can use to increase both work-family supervisor and work-family organizational support, such as training supervisors to be more work-family supportive. Increasing work-family specific supervisor support perceptions could also increase take up of work-family supportive policies, which in turn may lead employees to perceive the organizational climate as more work-family supportive, which relates to lower work-to-family conflict. This study shows how important it is for organizations to invest in selecting and developing managers who are able to provide positive workplace social support for employees generally on the job and for work-family specific issues.

**Conclusion**

Research on linkages between workplace social support and work-family conflict has increased dramatically over recent decades. Despite this expansion, more consolidation and agreement is needed in the work-family field on definitions, construct measurement, and recurring processes of study. Our study clearly shows that work-family
specific support is more strongly related to work to family conflict than general support. We also show both general and work-family specific supervisor support relates to work-family conflict via perceptions of work-family organizational support. Perceived organizational support and social support are well-researched theoretical domains that span a number of disciplines across the social sciences, which will provide a continued theoretical springboard for advancement of the work-family field. They also are constructs offering vehicles to mainstream work-family measurement and research questions to integrate with core human resource and organizational behavior measures.

Increased attention to work-family specific support will also enhance general effectiveness of human resource systems. Organizations are hiring increasing numbers of workers who are bringing their family demands with them while they are on the job. Given work-family conflict is associated with many health, well-being, and organizational outcomes (Eby et al., 2005; Kossek et al., 2010), by changing workplaces to be more socially supportive of positive work-family relationships, employment contexts serve a proactive role that shape critical employment and societal outcomes.
